

A decorative background graphic consisting of a network of interconnected nodes and lines. The nodes are represented by small circles, some of which are solid blue, some are solid grey, and some are hollow blue. The lines connecting them are thin and grey. The network is more dense on the left side and fades out towards the right.

Advanced CNN for computer vision

Rodrigo Gonzalez, PhD

Hello!

I am Rodrigo Gonzalez, PhD

You can find me at rodraz@gaail.com

Summary

1. The different branches of computer vision: image classification, image segmentation, object detection
2. Modern convnet architecture patterns: residual connections, batch normalization, depthwise separable convolutions

1.

Computer vision tasks

The goals of a CNN

Computer vision tasks

Target mask

Conv2DTranspose layer

```
from tensorflow import keras
from tensorflow.keras import layers
```

```
def get_model(img_size, num_classes):
    inputs = keras.Input(shape=img_size + (3,))
    x = layers.Rescaling(1./255)(inputs)
```

Don't forget to
rescale input
images to the
[0-1] range.

Note how we use
padding="same"
everywhere to avoid
the influence of border
padding on feature
map size.

```
x = layers.Conv2D(64, 3, strides=2, activation="relu", padding="same")(x)
x = layers.Conv2D(64, 3, activation="relu", padding="same")(x)
x = layers.Conv2D(128, 3, strides=2, activation="relu", padding="same")(x)
x = layers.Conv2D(128, 3, activation="relu", padding="same")(x)
x = layers.Conv2D(256, 3, strides=2, padding="same", activation="relu")(x)
x = layers.Conv2D(256, 3, activation="relu", padding="same")(x)
```

```
x = layers.Conv2DTranspose(256, 3, activation="relu", padding="same")(x)
x = layers.Conv2DTranspose(
    256, 3, activation="relu", padding="same", strides=2)(x)
x = layers.Conv2DTranspose(128, 3, activation="relu", padding="same")(x)
x = layers.Conv2DTranspose(
    128, 3, activation="relu", padding="same", strides=2)(x)
x = layers.Conv2DTranspose(64, 3, activation="relu", padding="same")(x)
x = layers.Conv2DTranspose(
    64, 3, activation="relu", padding="same", strides=2)(x)
```

```
outputs = layers.Conv2D(num_classes, 3, activation="softmax",
    padding="same")(x)
```

```
model = keras.Model(inputs, outputs)
return model
```

We end the model
with a per-pixel three-way

Conv2DTranspose layer

The output of the first half of the model is a feature map of shape (25, 25, 256).

But we want our final output to have the same shape as the target masks, (200, 200, 3)

We need to apply a kind of inverse of the transformations

Upsampling

Conv2DTranspose layer is a kind of convolution layer that learns to upsample.

```
(100, 100, 64) --> Conv2D(128, 3, strides=2, padding="same") --> (50, 50, 128) -->  
Conv2D-Transpose(64, 3, strides=2, padding="same") --> (100, 100, 64)
```

2.

Modern convnet architecture patterns

ImageNet Large Scale Visual Recognition Challenge (ILSVRC)

ILSVRC was an annual competition that used subsets of ImageNet and was designed to encourage the development and comparative evaluation of state-of-the-art algorithms.

The challenge tests were as follows:

- 1. Image classification:** predict the classes of objects present in an image.
- 2. Single object localization:** image classification + draw a bounding box around one example of each object present.
- 3. Object detection:** image classification + draw a bounding box around each object present.

Model architecture

A good model architecture is one that reduces the size of the **search space** or otherwise makes it easier to converge to a good point of the search space.

Model architecture is all about making the problem simpler for **gradient descent** to solve.

The VGG16 architecture

Figure 9.8 The VGG16 architecture: note the repeated layer blocks and the pyramid-like structure of the feature maps

The vanishing gradients problem

The *name of the game* is to adjust the parameters of each function in the chain based on the error recorded on the output of f_4 (the loss of the model).

To adjust f_1 , you'll need to percolate error information through f_2 , f_3 , and f_4 .

However, each successive function in the chain introduces some amount of noise.

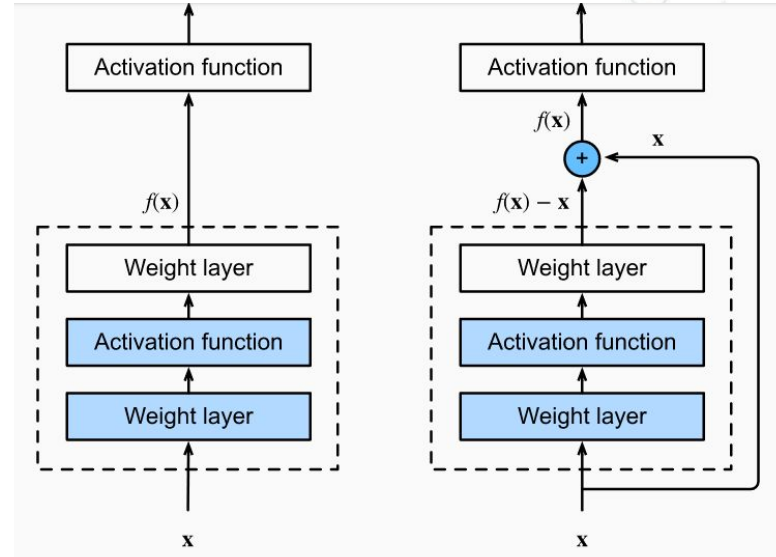

If your function chain is too deep, this noise starts overwhelming gradient information, and backpropagation stops working.

A residual connection

To solve the vanishing gradients problem, just force each function in the chain to retain a noiseless version of the information contained in the previous input.

This technique was introduced in 2015 with the ResNet family of models.

A residual connection

Listing 9.1 A residual connection in pseudocode

```
x = ...  
residual = x  
x = block(x)  
x = add([x, residual])
```

Some input tensor

Save a pointer to the original input. This is called the residual.

This computation block can potentially be destructive or noisy, and that's fine.

Add the original input to the layer's output: the final output will thus always preserve full information about the original input.

A residual connection

Listing 9.1 A residual connection in pseudocode

```
x = ...  
residual = x  
x = block(x)  
x = add([x, residual])
```

Some input tensor

Save a pointer to the original input. This is called the residual.

This computation block can potentially be destructive or noisy, and that's fine.

Add the original input to the layer's output: the final output will thus always preserve full information about the original input.

A residual connection

Listing 9.1 A residual connection in pseudocode

Some input
tensor

```
x = ...  
residual = x  
x = block(x)  
x = add([x, residual])
```

Add the original input to the
output: the final output
always preserve full info
about the original

Save a pointer to the
original input. This is
called the residual

Listing 9.2 Residual block where the number of filters changes

```
from tensorflow import keras  
from tensorflow.keras import layers  
  
inputs = keras.Input(shape=(32, 32, 3))  
x = layers.Conv2D(32, 3, activation="relu")(inputs)  
residual = x  
x = layers.Conv2D(64, 3, activation="relu", padding="same")(x)  
residual = layers.Conv2D(64, 1)(residual)  
x = layers.add([x, residual])
```

Now the block output and the
residual have the same shape
and can be added.

This is the layer around which we create
a residual connection: it increases the
number of output filters from 32 to 64.
Note that we use padding="same"
to avoid downsampling
due to padding.

The residual only had 32
filters, so we use a 1×1
Conv2D to project it to the
correct shape.

Batch normalization

In previous examples, data was normalized before feeding it into models.

```
normalized_data = (data - np.mean(data, axis=...)) / np.std(data, axis=...)
```

Even if the **data entering** a Dense or Conv2D network has a 0 mean and unit variance, there's no reason to expect a priori that this will be the case for the **data coming out**.

Layer `BatchNormalization` in Keras do the job.

The main effect of batch normalization **appears** to be that it helps with gradient propagation.

Batch normalization

Batch normalization

Because the normalization step will take care of centering the layer's output on zero, the **bias vector** is **no longer needed** when using `BatchNormalization`.

```
x = ...  
x = layers.Conv2D(32, 3, use_bias=False)(x)  
x = layers.BatchNormalization()(x)
```

Recommended setup:

```
x = layers.Conv2D(32, 3, use_bias=False)(x)  
x = layers.BatchNormalization()(x)  
x = layers.Activation("relu")(x)
```

**We place the activation after the
BatchNormalization layer.**

Batch normalization will center your inputs on zero, while your relu activation uses zero as a pivot for keeping or dropping activated channels

A decorative network diagram in the top-left corner, featuring a complex web of interconnected nodes and lines. The nodes are represented by small circles, some of which are larger and have concentric circles, while others are smaller and solid. The lines are thin and gray, connecting the nodes in a non-linear fashion.
